

Public Opinion Research Project

This repository has been repositioned as a professional survey-analytics capstone blueprint. Instead of pretending the analysis already exists, it now presents a clear research purpose, a hypothesis matrix, and a realistic delivery workflow that can absorb a public-opinion dataset without restructuring the project from scratch.

Fake claims about results or model performance

Purpose and methodological direction

The project is designed to study how economic expectations, institutional trust, issue salience, and sociodemographic differences shape political attitudes and behavior.

Responsible positioning: this is a ready-to-execute research design, not yet a finished empirical case.

- Hypothesis 1 links economic expectations with approval and vote intention.
- Hypothesis 2 tests whether institutional trust predicts turnout and policy legitimacy.
- Hypothesis 3 uses issue salience to segment the electorate into interpretable clusters.
- Hypothesis 4 adds subgroup analysis to avoid one-size-fits-all political conclusions.

What was added

The repository now includes executable code that generates a hypothesis matrix, a deliverable roadmap, and a visual workflow. That gives the project a technical foundation even before the final dataset is loaded.

Current conclusion

The main improvement is strategic rather than statistical. This repository no longer looks unfinished; it now looks prepared. That matters because a professional portfolio should show not only final results, but also the ability to define a serious analytical project before execution begins.

Portfolio takeaway: the project is now credible as a capstone-in-preparation, and it can become an empirical case quickly once the source survey is chosen.
